A. OBJECTIVES

Glaucoma (Fig. 1) is a disease affecting millions of people in the US alone every year. Elevated intraocular pressure (IOP), the most common cause of glaucoma, slowly kills the optic nerve starting from the outside and progressing to the inside. Not surprisingly, this manifests itself at first in peripheral visual field loss. A novel computer-automated visual field test that is capable of detecting early glaucomatous visual-field loss has recently been developed jointly by Caltech and USC [1-6]. If untreated, glaucoma leads to blindness. In general, glaucomatous visual-field loss is considered irreversible. The usual treatment for glaucoma can be as simple as administering eye drops.

There are a number of external eye-pressure-measuring devices (e.g., Tono-pen) in existence. The problem with most of them is that they are fairly imprecise (e.g., dependent on corneal thickness and elasticity) and/or can only be administered at a doctor's office. For example, non-contact tonometry using pneumatic systems ("air-puff") is very dependent on the eye wall and corneal rigidity and can be grossly wrong because these factors are not taken into account. Therefore, systems based on non-contact tonometry are not good screening devices. All other technologies require touching something to the eyeball (i.e., cornea) and thus can only be done in an ophthalmologist's or optometrist's office.

More realistic IOP measurements can be obtained from within the eye. A variety of devices for this purpose have been proposed or developed in the recent past [7-13]. However, none of the micromachined devices are being used as a standard method to measure IOP because they are too invasive to be implanted and/or have not been validated in a realistic variable-pressure environment (e.g., animal eye).

It is known that the IOP within the same eye of a person undergoes drastic changes (oscillations) during the 24 hours in a day (Fig. 2); thus a pressure measurement at a doctor's office can at best only get a snapshot in time of the currently prevailing intraocular pressure, missing all the other oscillations. Consequently a sporadic IOP measurement may still not prevent glaucomatous damage from happening.

A self-checking non-contact IOP-monitoring system with daily readout that measures the true intraocular pressure is very important and much needed. Beyond the screening for high IOP, there are issues related to drug therapy for glaucoma and how to titrate and monitor these treatments: While on therapeutic eye drops, one often sees salient and transient periods of breakthrough elevation of the IOP which can damage the eye. Therefore we would like our proposed wireless intraocular-pressure sensor (WIPS) to red-flag even one such violation. This close monitoring of the IOP would greatly help the control and optimization of glaucoma drug therapy, especially for patients who already have the diagnosis of glaucoma.

From a JPL-NASA point of view, the proposal addresses an important aspect of human space flight: According to the Space Medicine Office at NASA's Johnson Space Center, intraocular hypertension and intracranial hypertension due to microgravity are known problems in the operative environment of space flight. Thus, monitoring IOP is essential for long-duration space missions, and enhances the chances for timely countermeasures before astronaut performance is impaired or permanent damage encountered.

Our proposed goal is to develop, as a first step, a prototype of a pressure sensor that in the end would be accurate and small enough to be implantable in the eye, to monitor the intraocular pressure continuously or on demand.

B. PROGRESS AND RESULTS

Goals of DRDF proposal accomplished:

- Creation of a Breadboard test bed (Fig. 3)
- Creation of a Breadboard design (non-implantable, Fig. 4) consisting of a commercial-off-the-shelf (COTS) pressure sensor and a low-power and wireless readout circuit for measuring the intraocular pressure
- Creation of a Brassboard test bed (Fig. 5)
- Creation of a Brassboard design (non-implantable, Fig. 6) consisting of a COTS pressure sensor and an integrated low-power and wireless readout circuit
- Several alternative/additional circuit designs have been investigated.

C. SIGNIFICANCE OF RESULTS

This task developed the foundation for an implantable wireless intraocular-pressure-sensing device and paved the way for the future development of an implantable intraocular-pressure controller that would automatically control the IOP and keep it below a preset level at all times, thus preventing the onset or progression of glaucoma.

D. FINANCIAL STATUS

The total funding for this task was \$50,000 all of which has been expended.

E. PERSONNEL

No other personnel were involved.
